

# Precision Astronomy with Fully Depleted CCDs

2014

## Summary

Tony Tyson

# The connection to science

Rachel Mandelbaum

Model errors in shapes as a multiplicative bias, additive term:

$$\gamma_{\text{meas}} = (1+m) \gamma_{\text{true}} + c$$

(Ideally  $m=c=0$ )

Cosmic shear (shear-shear correlation):

$$\langle \gamma_{\text{meas}} \gamma_{\text{meas}} \rangle = (1+m)^2 \langle \gamma_{\text{true}} \gamma_{\text{true}} \rangle + 2 (1+m) \cancel{\langle c \gamma_{\text{true}} \rangle} + \cancel{\langle c c \rangle}$$

↑  
Calibration bias

Additive term  
(diagnosable with star-galaxy cross-correlations)

# The connection to science

Rachel Mandelbaum

Model errors in shapes as a multiplicative bias, additive term:

$$\gamma_{\text{meas}} = (1+m) \gamma_{\text{true}} + c$$

(Ideally  $m=c=0$ )

$< 3E-4$

$< 3E-3$

Cosmic shear (shear-shear correlation):

$$\langle \gamma_{\text{meas}} \gamma_{\text{meas}} \rangle = (1+m)^2 \langle \gamma_{\text{true}} \gamma_{\text{true}} \rangle + 2 (1+m) \cancel{\langle c \gamma_{\text{true}} \rangle} + \cancel{\langle c c \rangle}$$

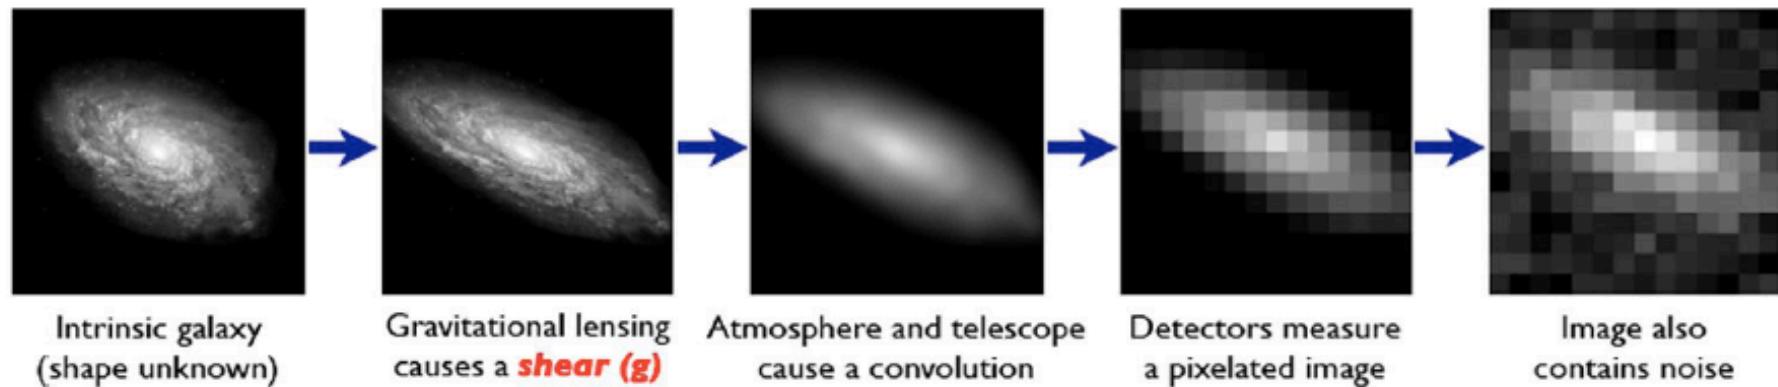

↑  
Calibration bias

Additive term  
(diagnosable with star-galaxy cross-correlations)

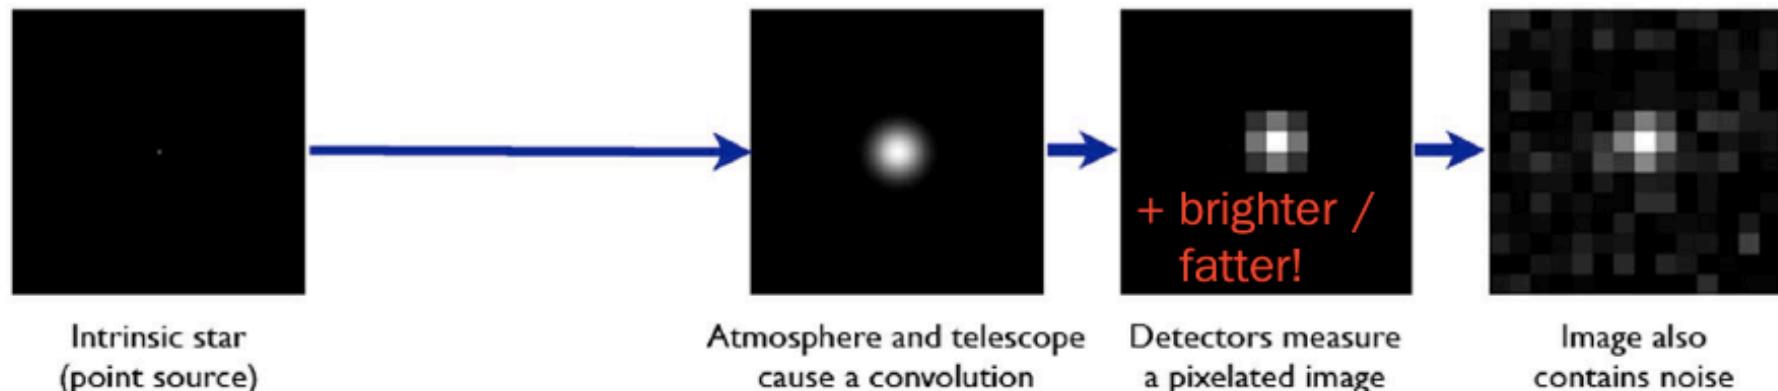

# Examples of where systematics come in

- Chromatic effects: PSF for stars is different from that for galaxies, or even within different parts of the same galaxy.
- Brighter-fatter effect: PSF for bright stars is fatter than that for the galaxies.
- Tree rings, edge distortion: astrometry (a remapping that isn't a convolution)
- Cosmic rays: basic measurement issue
- Defects can lead to coherent selection effects

## Galaxies: Intrinsic galaxy shapes to measured image:

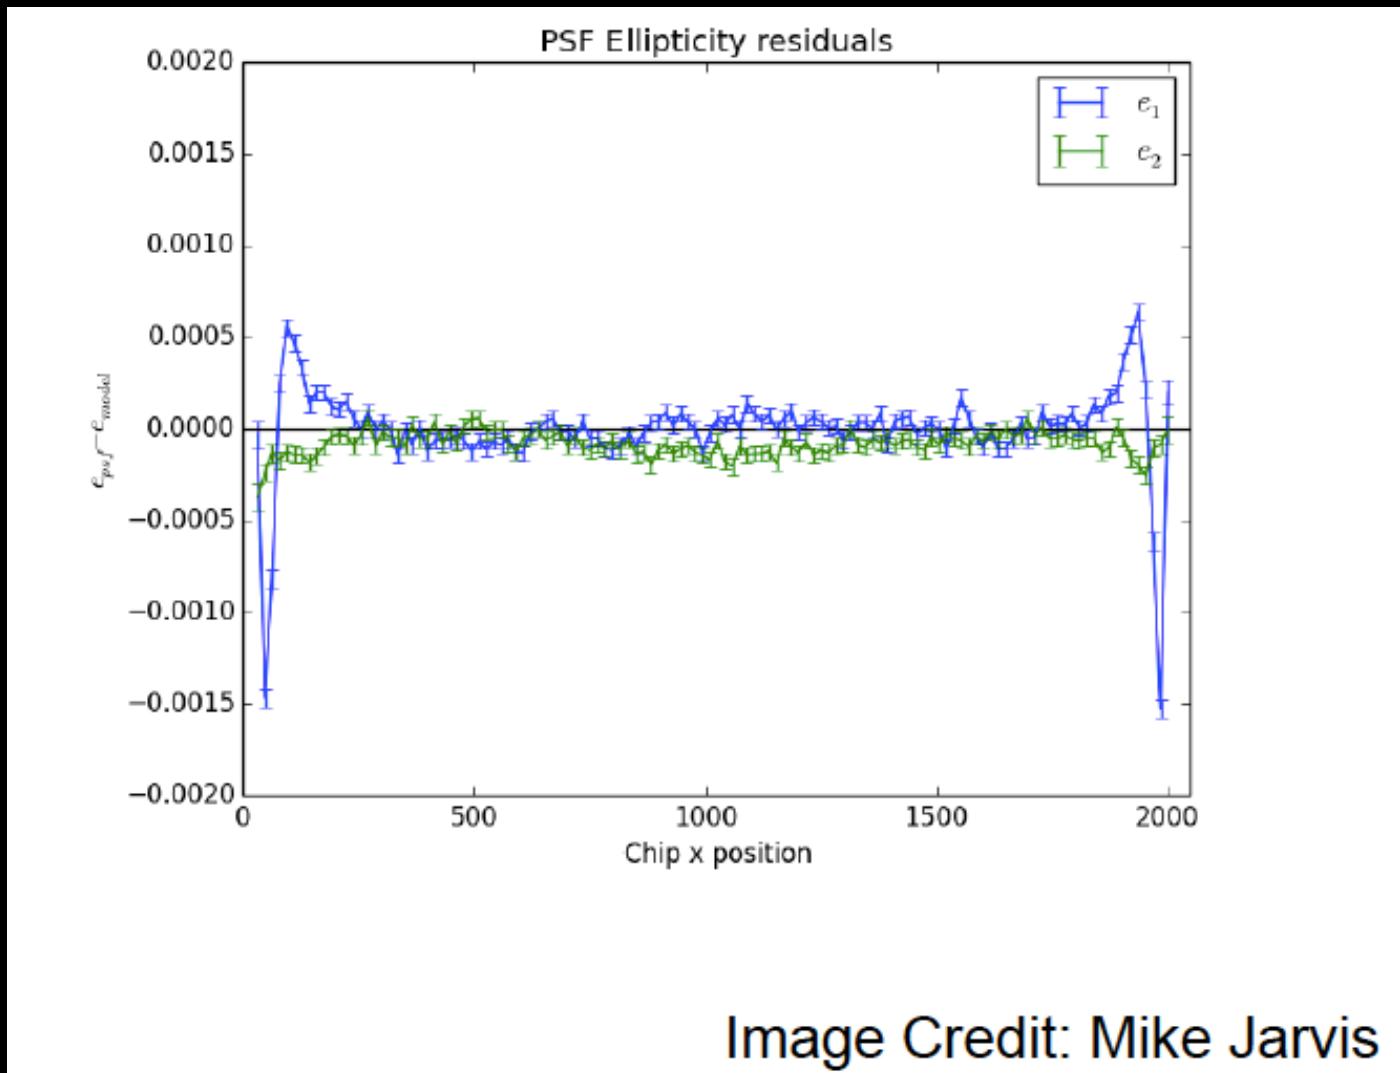

## Stars: Point sources to star images:

CCD N22 (53)

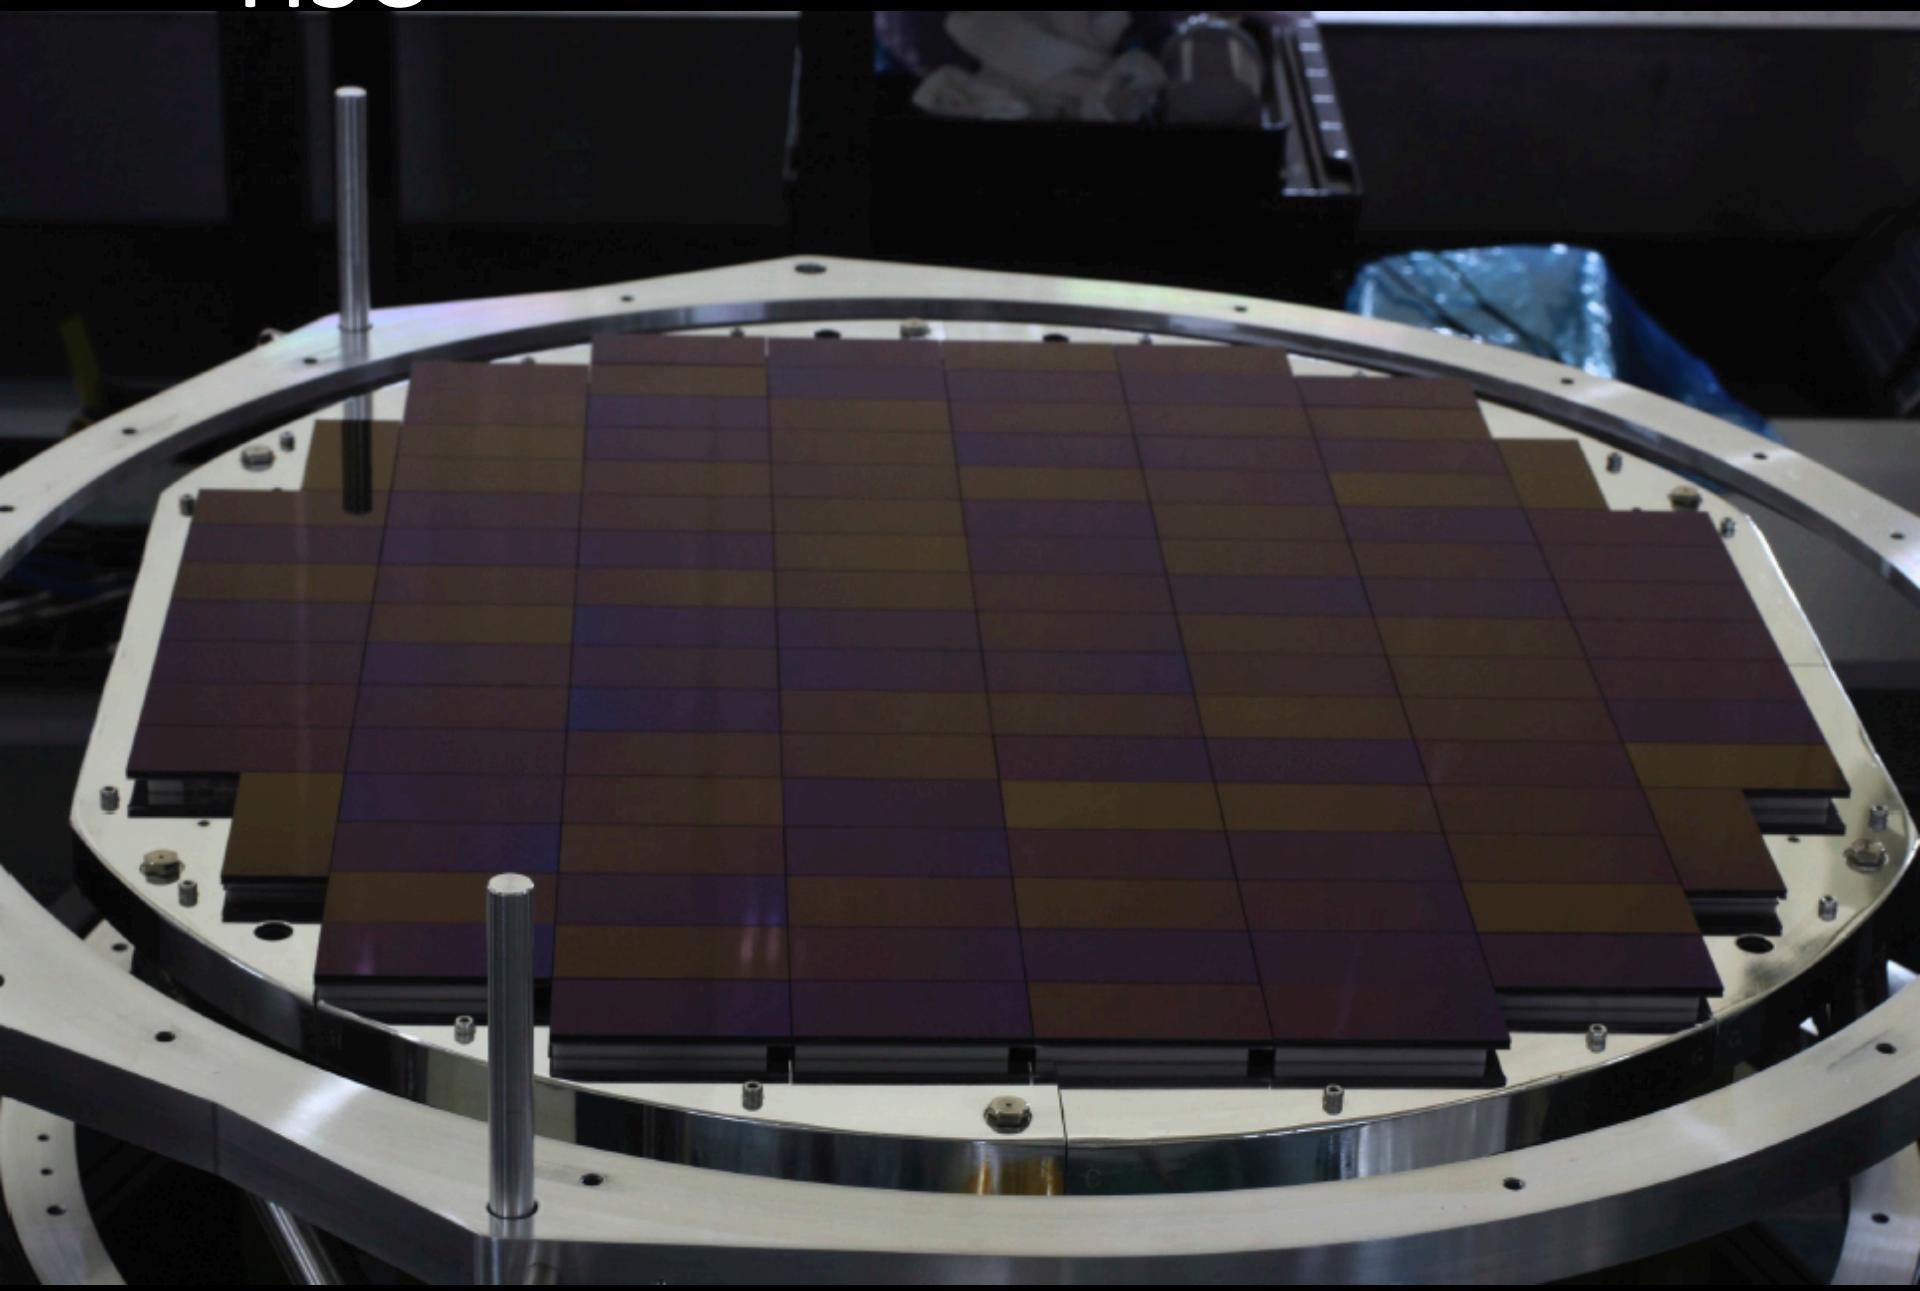

Pierre Astier

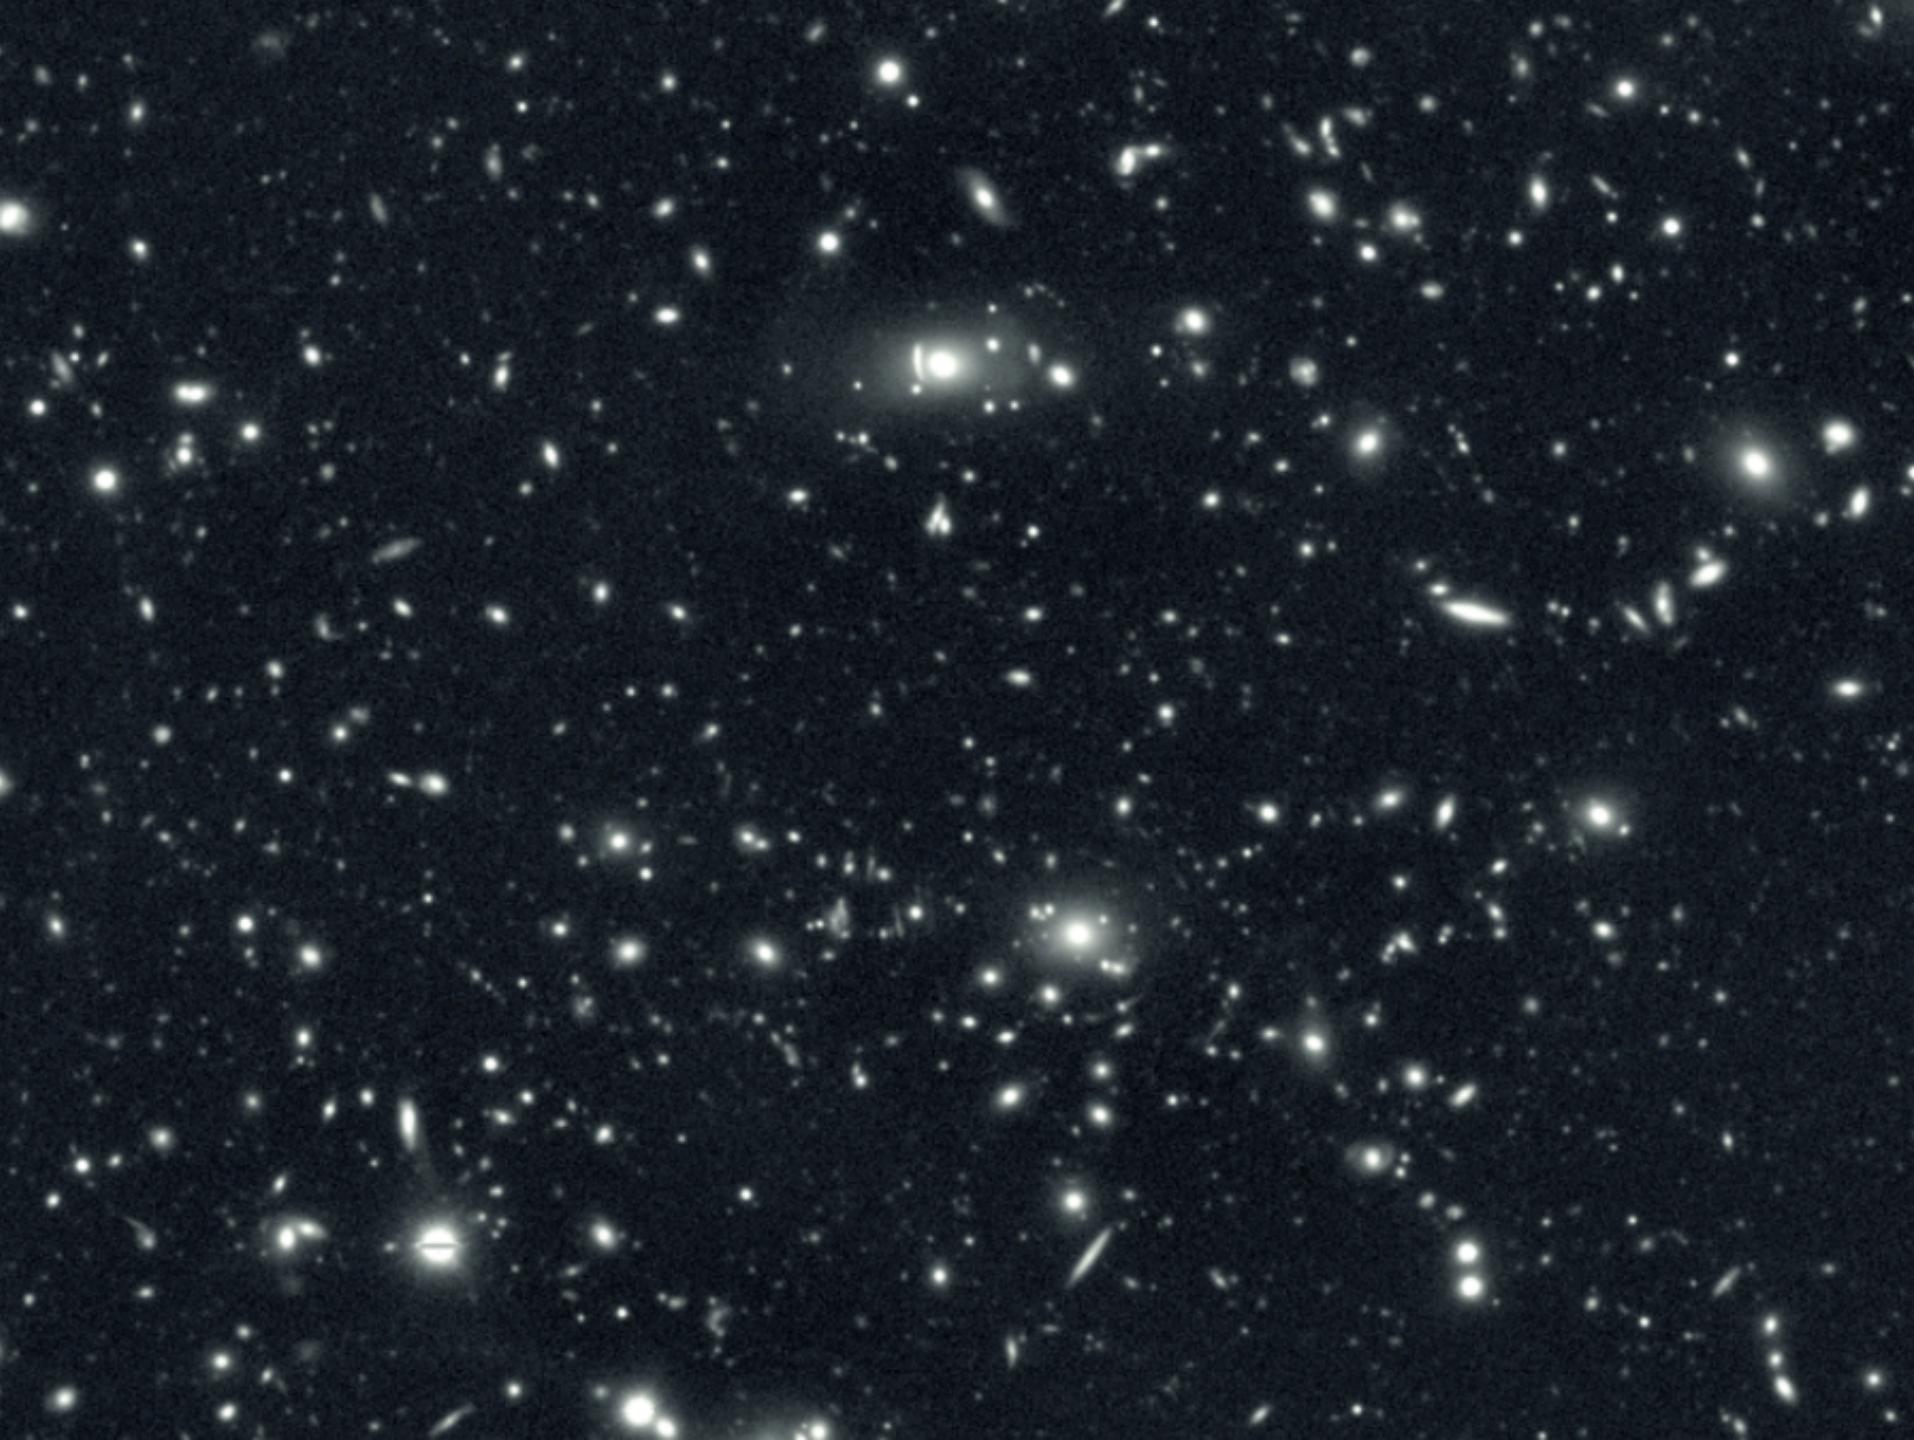

- The stored charge pattern distorts the **average drift lines**
- It also decreases the drift electric field, and hence increases **lateral diffusion** (S. Holland).

HSC

Satoshi Miyazaki

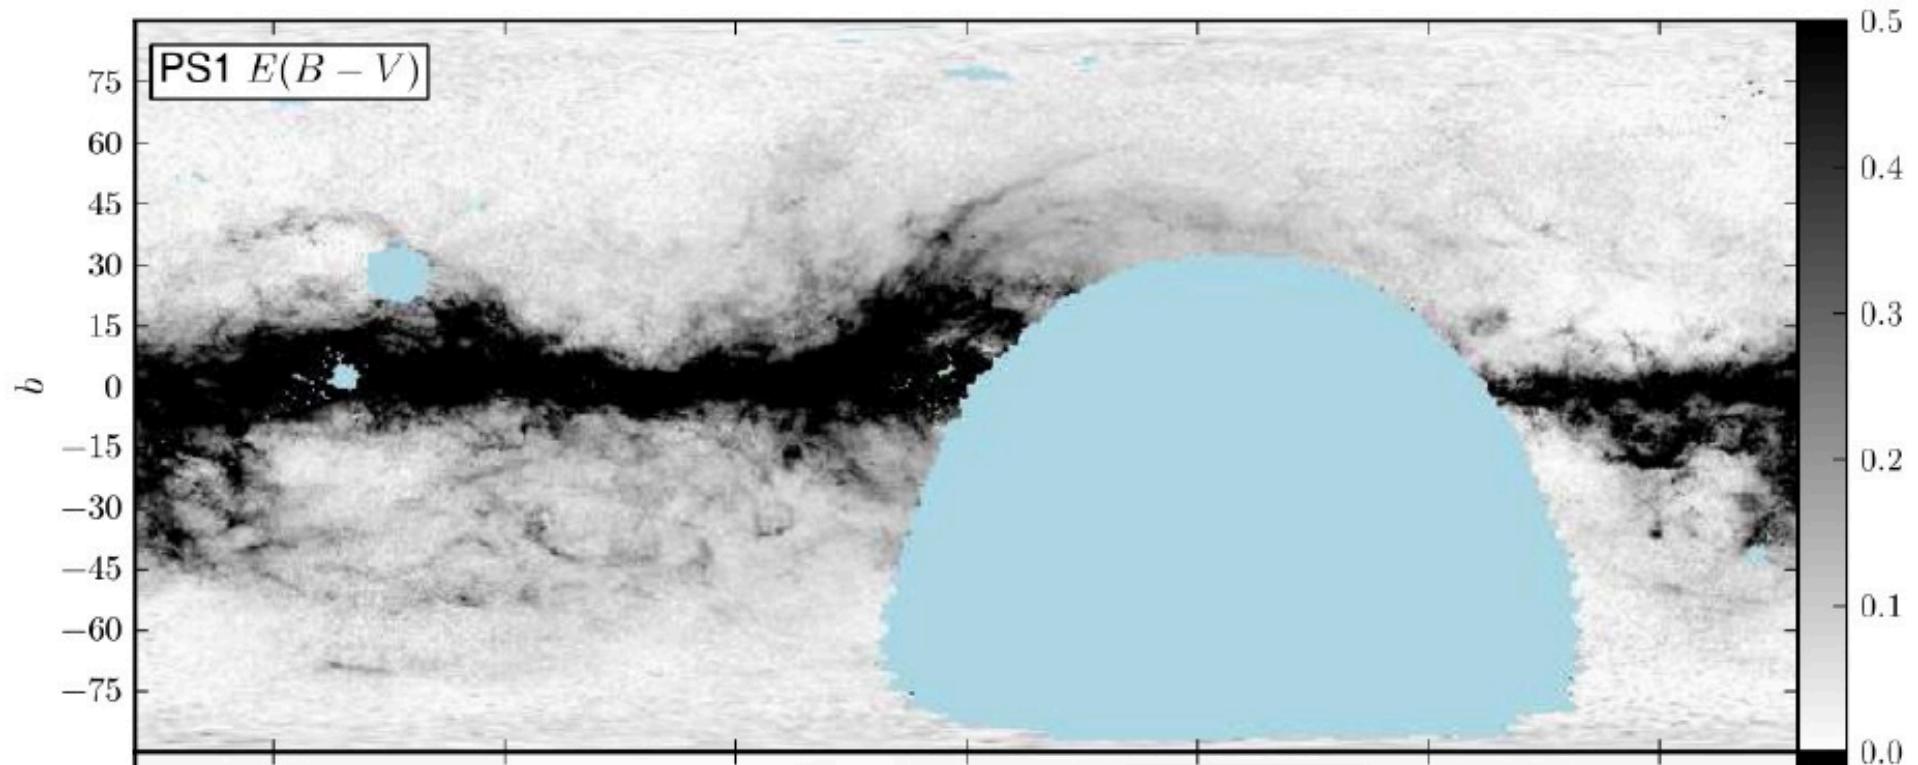

# PanSTARRS

Gene Manier

3D Dust map

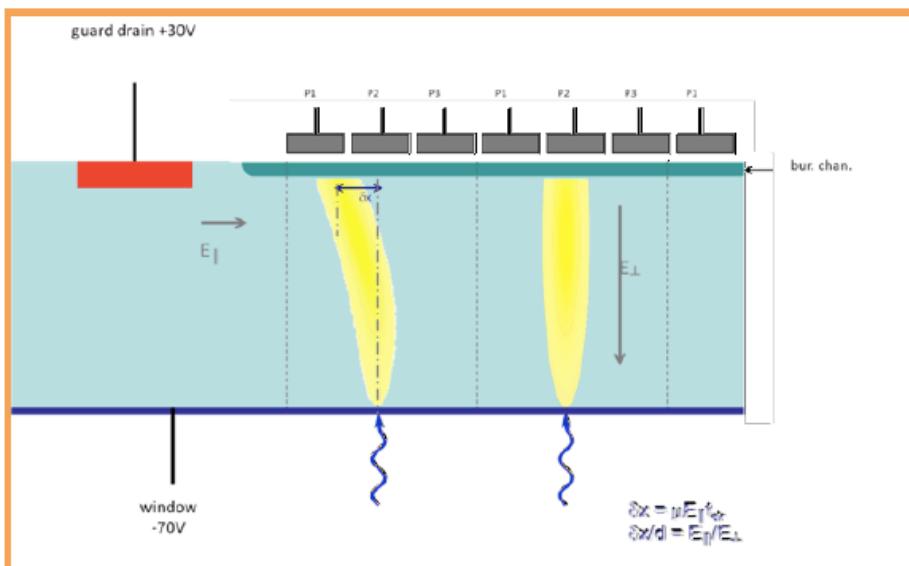

2.8 billion objects

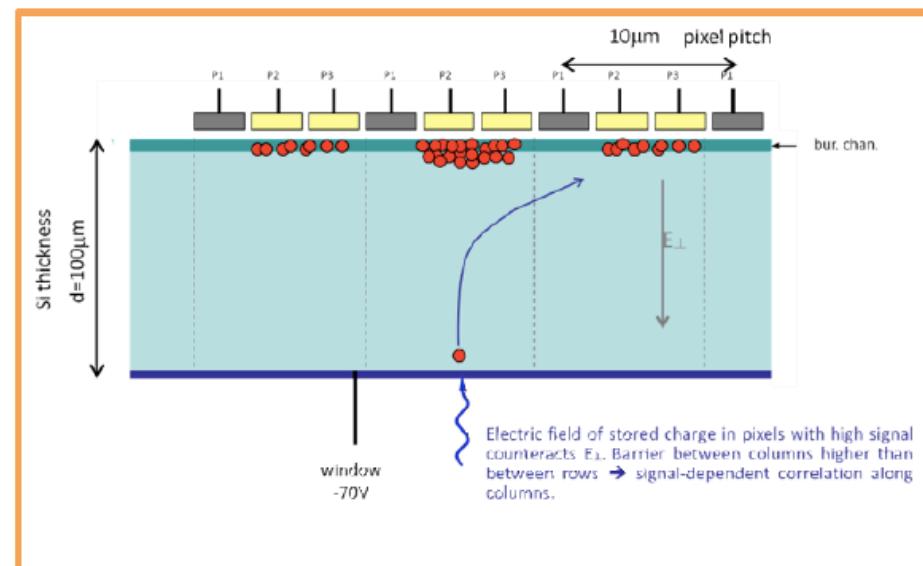

# LSST sensors

Andrei Nomerotski

Static : edge effects, tree-rings

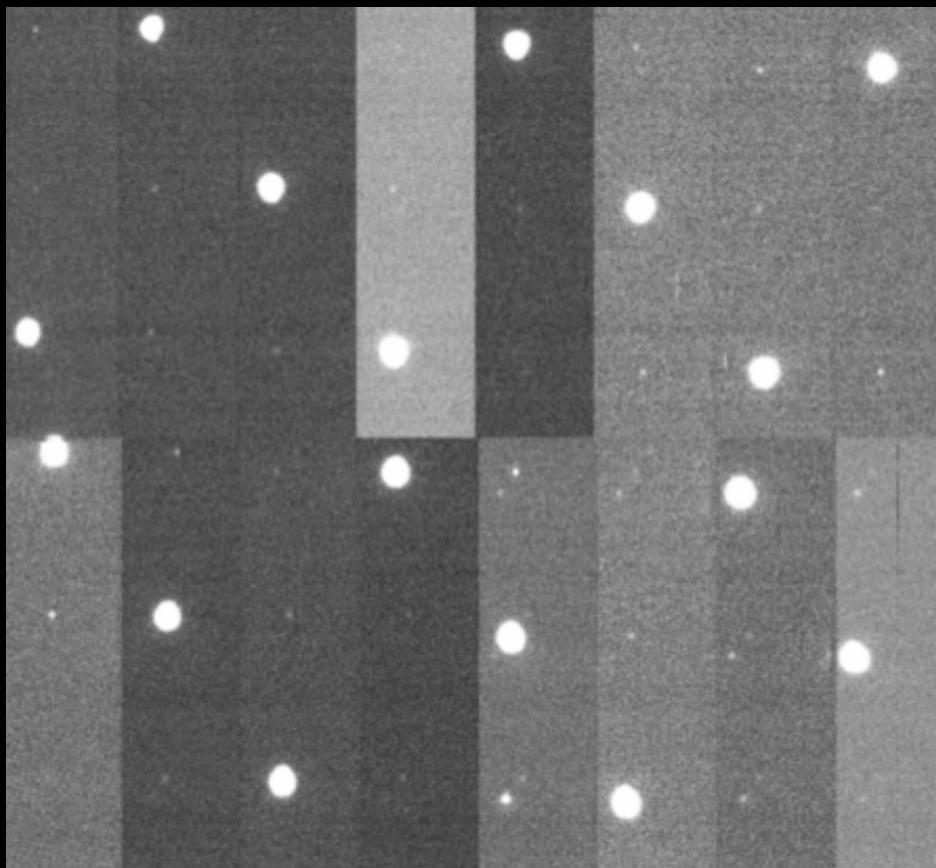

“Dynamic” : brighter-fatter effect

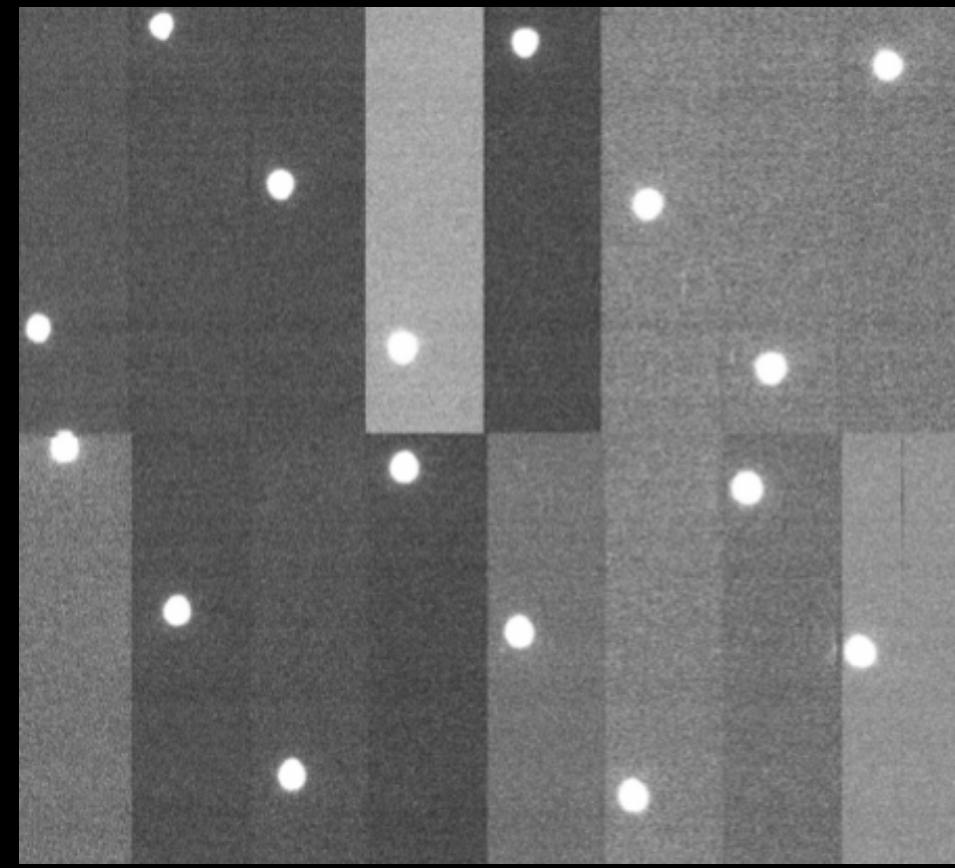

# Crosstalk

Before correction

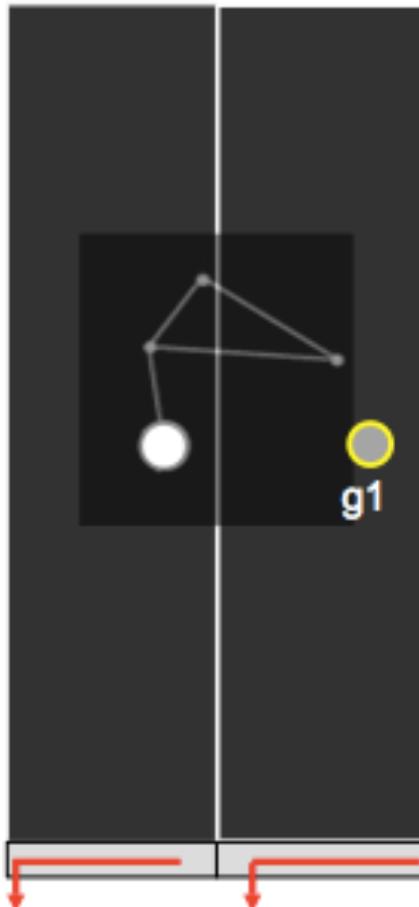

After correction

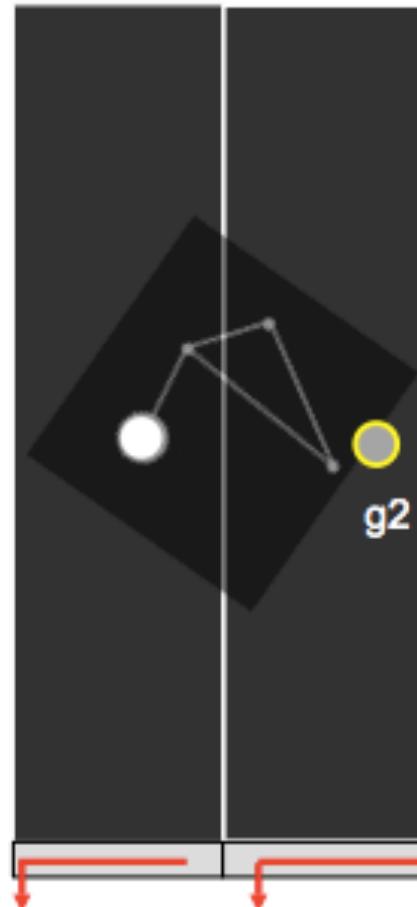

# rotation

## Coadd dithered images with rotation

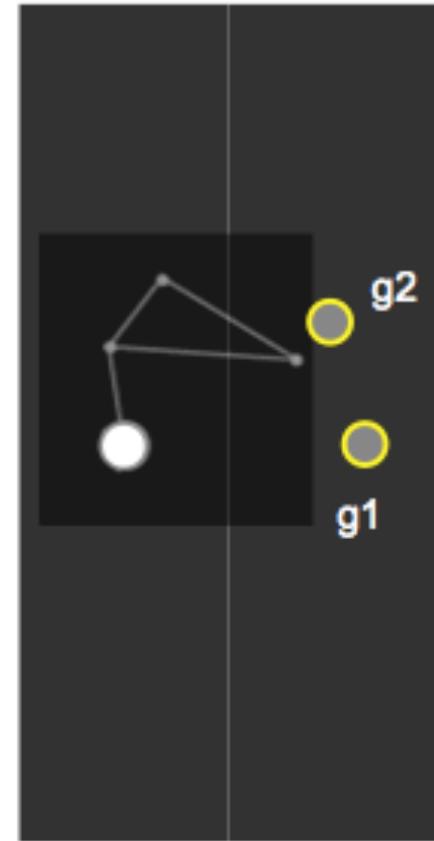

exposure 1

exposure 2

registered and coadded

# DECam

Daniel Gruen

- brighter-fatter effect independent of photon rate
- Flat field pixel covariance is lot dependent

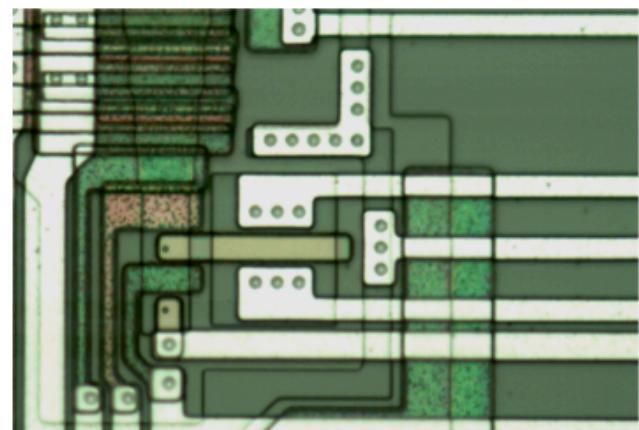

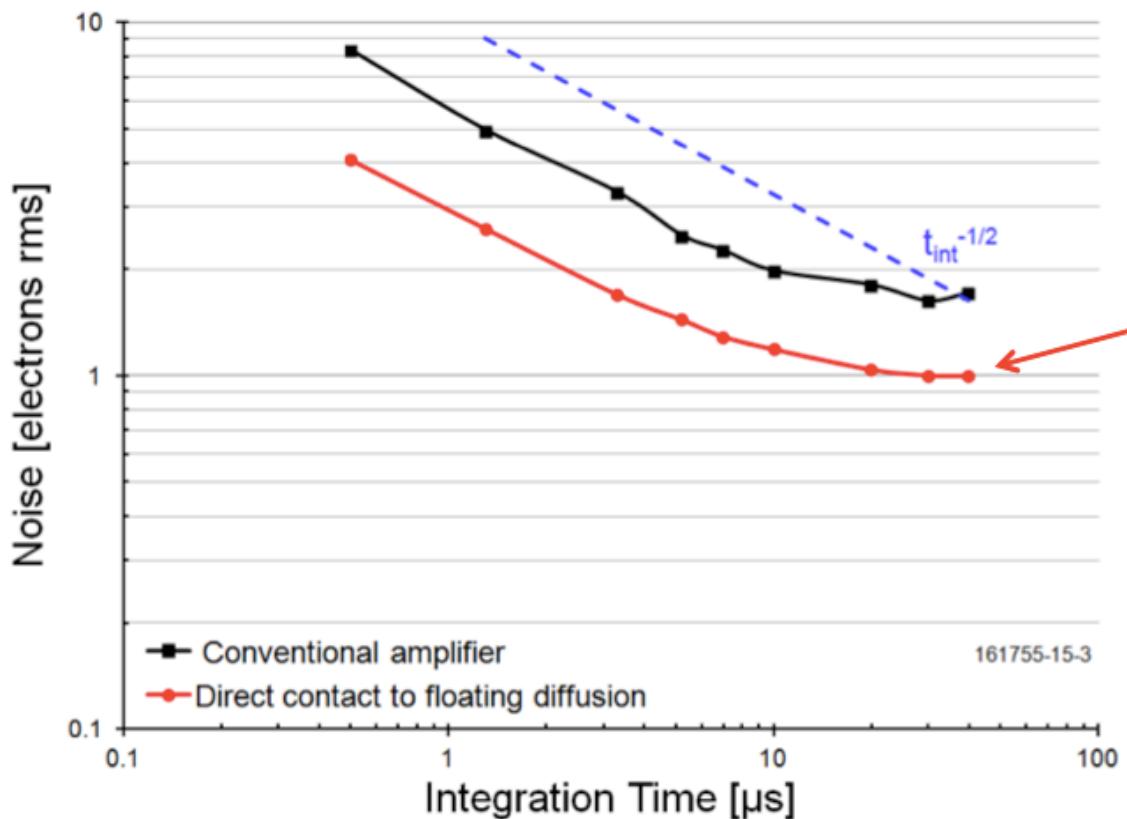

# Euclid CCDs

Douglas Jordan

- Radiation induced traps act on a particular volume so it follows that by reducing the interaction volume, one could reduce the frequency of traps → Build the device with a thinner register channel.
- Introduce a charge injection structure to fill traps with a “fat zero” prior to readout.

# DESI CCDs

Steve Holland

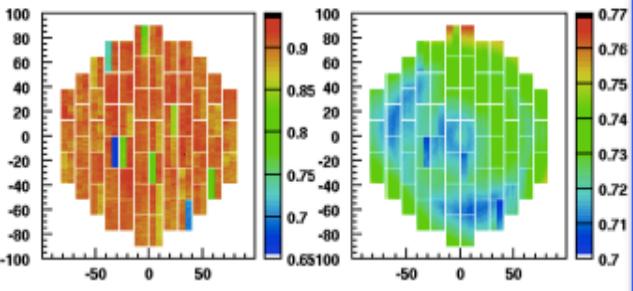

# Ghosts

- CFHTLS      Nicolas Regnault
- DEC           William Wester

# Filter edges matter

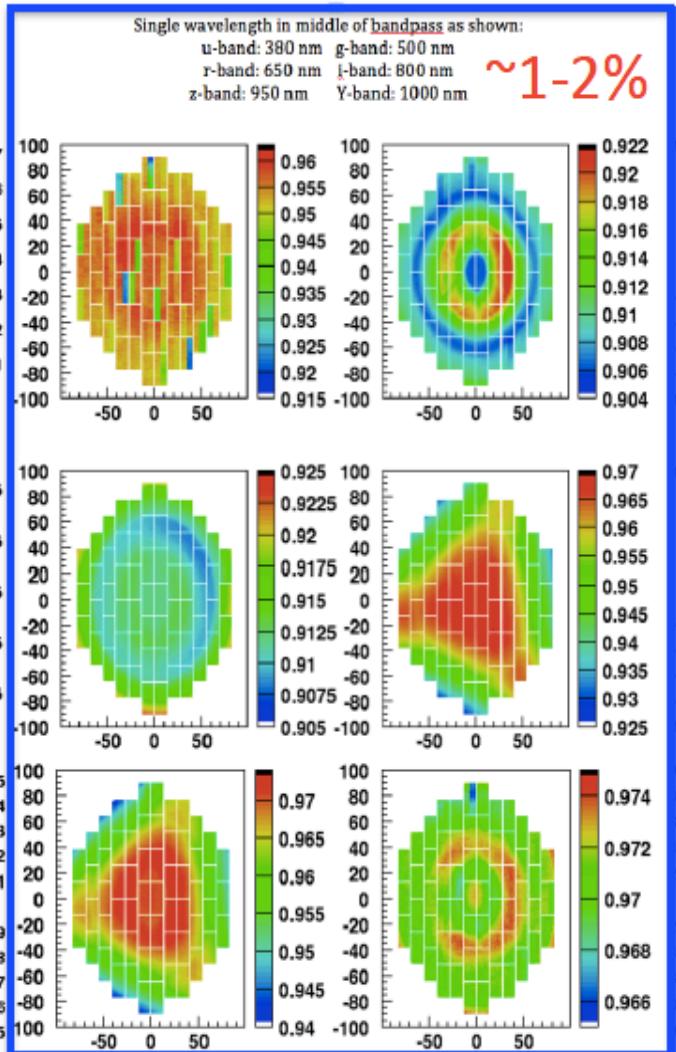

Single wavelength on rising edge as shown:  
 u-band: 350nm g-band: 450nm  
 r-band: 570nm i-band: 710nm  
 z-band: 850nm Y-band: 950 nm

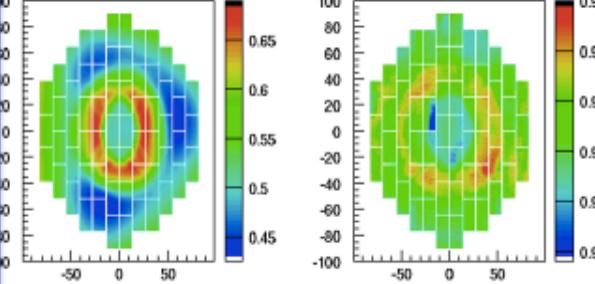

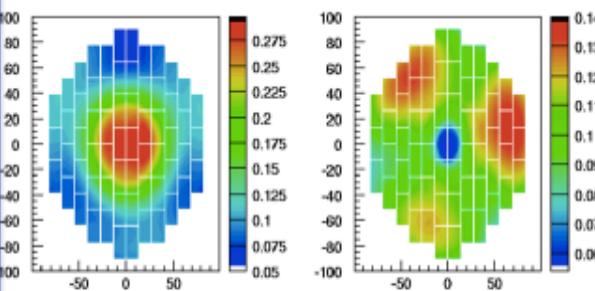

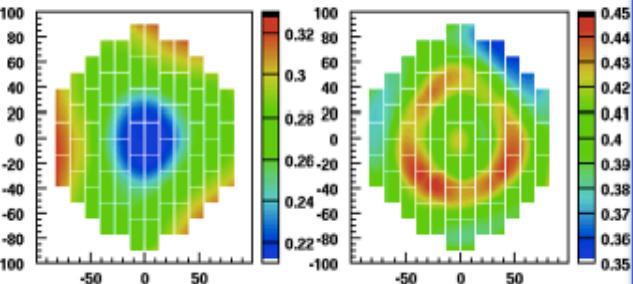

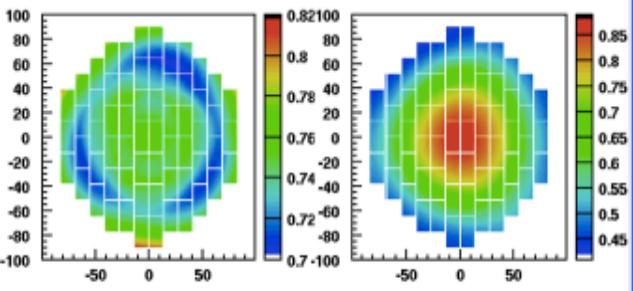

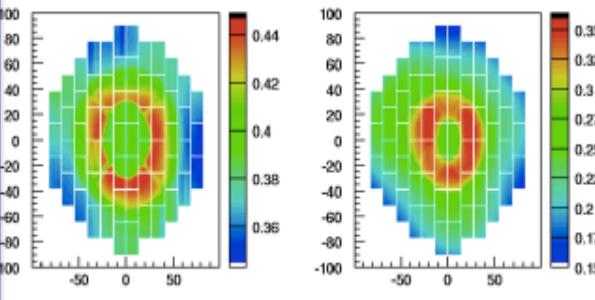

~10%

Single wavelength in middle of bandpass as shown:

u-band: 380 nm g-band: 500 nm  
 r-band: 650 nm i-band: 800 nm  
 z-band: 950 nm Y-band: 1000 nm

Single wavelength on falling edge as shown:  
 u-band: 400nm g-band: 550nm  
 r-band: 720nm i-band: 860nm  
 z-band: 1000nm Y-band: 1040 nm

# Astrometric & photometric calibration

Robert Lupton

The number of detected counts  $C_{raw,b}$  from an astronomical source with flux  $F_\nu$  in band  $b$  is

$$C_{raw,b} \propto \int_0^\infty F_\nu(\lambda) S^{atm}(\lambda) S_b^{sys}(\lambda) d\lambda / \lambda$$

where "detected" means photons which are measured as part of the object, as opposed to those spread out over the focal plane by scattering and ghosting.

We are interested in  $S^{atm}$  and  $S_b^{sys}$ , the probabilities of a photon passing through the atmosphere and through the telescope/camera and being detected.

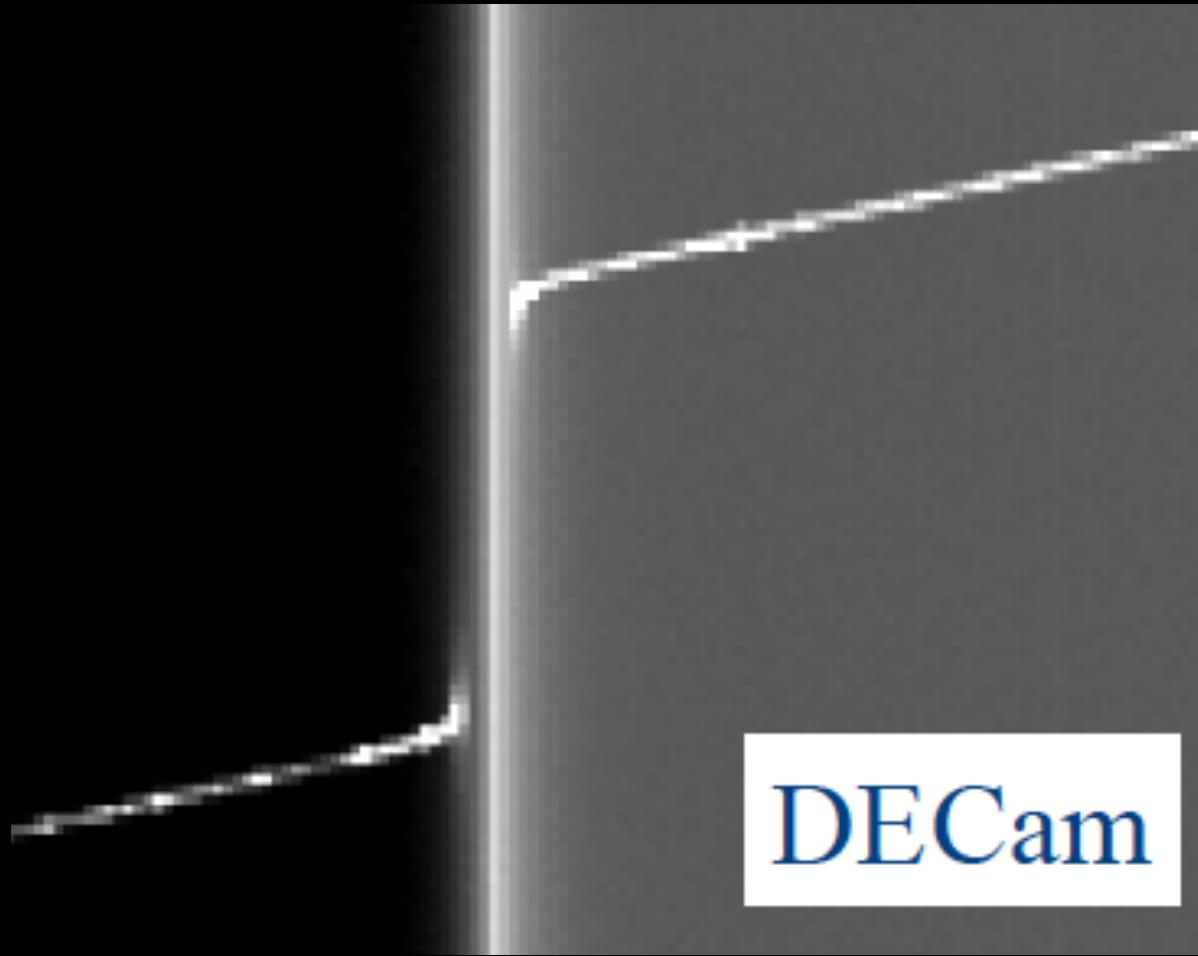

We need to find

$$C_{std,b} \equiv \int_0^\infty F_\nu S_{std,b} d\lambda / \lambda$$

given  $C_{raw,b}$  (where  $S_{std,b}$  is some average  $S^{atm} S_b^{sys}$ ).

Uses clever projection system designed by Chris Stubbs

# CCD characterization with muons

Merlin Fisher-Levine

- How do you characterize the uncertainty in your estimate of the PSF? Can you predict the posterior and marginalize for science?
- This will depend on how well your basis set can model the PSF.
- Quite a bit of recent work in this area (see Schneider et al. 2014)
- Need to consider computational feasibility.

# Phosim CCD simulations

Chris Walter

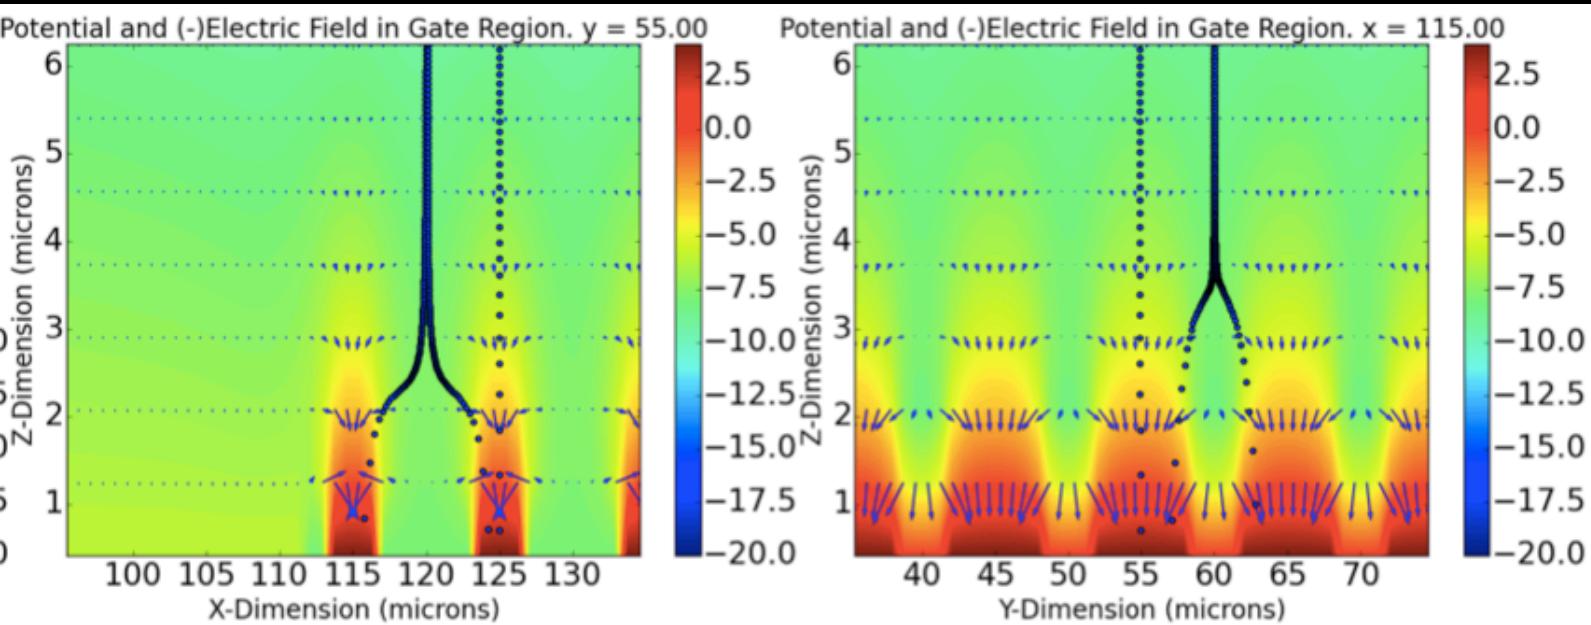

model as dipole or potential from gate voltage plus space charge?

# Use all information

- Many of the current efforts on CCD systematics reduction rely on observational data from telescope operations.
- We should certainly use everything we can know about these CCDs from lab measurements, taken under realistic conditions.

# Use known information

Craig Lage

Known geometry and voltages

# LSST f1.2 beam simulator Illuminates full CCD.

arXiv:1411.5667

# Characterization priorities

- Sub-pixel studies
- Study CCD effects vs sky background
- All vs wavelength
- Find copy of Jackson
- Further develop models of charge transport
- Explore clock and bias voltages, settling times
- Null tests; confirm removal of PSF systematics
- Undertake lab simulated observing
- Can we measure the science signals?
- What is the residual error?

# What if we don't correct for systematics? Simulated LSST survey with only CCD effects on

$\kappa$  (mass overdensity) map  
made from residual  
CCD shear systematics,  
in dithered and rotated  
observations.

# Two Nobel prize nominations

- Chris Stubbs: for discovery of variable electron charge.
- Steve Holland: for operation at -150K without inverting population

# Most memorable comment

“Phosim doesn’t have to be correct, but it shouldn’t be wrong”

Robert Lupton
